Abstract: In this paper an adaptive fuzzy PI controller with feedback linearizing method is implemented to control torque and flux separately in induction motor. In this paper first decoupling of torque and flux which are outputs to be controlled, is achieved by using feedback linearization methodology. Then for reducing the effect of noise and rejection of disturbance, main part of controller which is adaptive PI fuzzy controller, is designed. Coefficients of PI controller are determined by defined fuzzy rules due to error dynamic. Inputs of fuzzy system are defined sliding surfaces which consist of torque and flux errors. The main contribution of this paper is effect reduction of noise and disturbance on torque and flux which is based on fuzzy logic and nonlinear control. At last the effectiveness of the proposed control scheme in presence of noise and load disturbance is simulated and comprised to applying sliding method. The results verify better effectiveness of the proposed method for effect reduction of noise and disturbance.

Keywords: Induction motor, Feedback linearizing, Fuzzy, PI controller

1. INTRODUCTION

The induction motors have been extensively applied in industry because of the advantages of simple construction, ruggedness, reliability, the minimum maintenance and low cost. This kind of motor has a very nonlinear system. In addition two main parameters of induction motor which are defined as torque and flux must be decoupled from each other for controlling separately. The decoupled control approaches, such as field-oriented control and nonlinear state feedback linearizing technique have been widely used in the design of induction motor derives for high-performance applications.

In the field-oriented method, the decoupled relationship is obtained by means of a proper selection of state coordinates, under the hypothesis that the rotor flux is kept constant [1], [2]. Nonlinear-state feedback control utilizes the feedback-linearization approach, which can achieve input-output decoupling control and good dynamic performance for induction motors [3], [4]. However, though the decoupled condition is always satisfied, the parameters of the controlled plant must be precisely known and accurate information on the rotor or secondary flux is required.

Sliding mode control (SLMC) has been shown to be an effective way for controlling electric drive systems. It is a robust control because the high-gain feedback control input cancels nonlinearities, uncertainty parameters, and external disturbances. It also offers a fast dynamic response, a stable control system and an easy hardware/software implementation. This control strategy offers some drawbacks associated with the large torque chattering that appears in a steady state, which may excite mechanical resonance. Fuzzy-logic, first proposed by L. A. Zadeh, has recently received a great deal of attention. The easy way of defining a fuzzy controller by rules with an obvious physical meaning has helped to expand this control technique. When it is applied to control nonlinear systems, this nonlinear control strategy has shown better results than classical controllers do [5].

In this paper first torque and flux are decoupled and nonlinear terms of motor is cancelled by applying feedback linearizing method. The main objective of this paper is to implement PI fuzzy controller which its inputs are sliding surfaces which are made of error dynamics. Main benefits of this approach are its robustness to system disturbance and input noise and uncertainty in system.

2. Induction motor model

Under assumption of linearity a three phase induction motor model in d-q stationary reference frame can be described by the following differential equations [6]:

$$\dot{x} = f(x) + u_d g_1 + u_q g_2$$

(1)

Where $x = [\phi_r, x_r, x_q, x_d]^T$, $u = [\psi_d, \psi_q, \psi_{dq}]$,

$$f(x) = \begin{bmatrix}
-\alpha_r + \beta x_r + w_p \phi_d \\
-\alpha_q - w_p \phi_q + \beta x_q \\
\frac{L_m}{T_r} x_r - \frac{1}{T_r} x_d - w_p x_q \\
\frac{L_m}{T_r} x_q + w_p x_r - \frac{1}{T_r} x_q
\end{bmatrix}$$

(2)

$$g_1 = \begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0
\end{bmatrix}$$

(3)

$$\alpha = \frac{R_m}{L_m}, \quad \beta = \frac{R_m L_m}{L_r}, \quad \gamma = \frac{L_m}{L_r}$$

(4)

Also Torque and flux are described as:

$$T_s = \frac{3}{2} \frac{p}{2} \frac{L_m}{L_r} (\psi_d \psi_q - \psi_q \psi_d)$$

(6)

$$\psi_q^* = \psi_q^* + \psi_q^*$$

(7)
As it is clear there is nonlinear relationship between torque and flux and state variables and it is difficult to control them separately. So feedback linearizing control (FLC) is applied to decouple them.

3. Controller design

Figure 1 presents main schematic of proposed controller.

3.1 Decoupling torque and flux

In this part of paper in order to control torque $T_c$ and square rotor flux $\psi_r^2$, the output equations are chosen as:

$$ y = \begin{bmatrix} h_1(x) \\ h_2(x) \end{bmatrix} = \begin{bmatrix} T_c \\ \psi_r^2 \end{bmatrix} = \begin{bmatrix} \frac{3 p T_m}{2} \left( \psi_r \dot{\psi}_r - \psi_r \dot{\psi}_r \right) \\ \frac{3 p T_m}{2} \left( \psi_r \dot{\psi}_r + \dot{\psi}_r \right) \end{bmatrix} $$

To obtain linear relationship between output and states of coordinate transformation by using feedback linearization a subset of the new state variables of the coordinate transformation can be chosen according to Eq.(8). So definition of the new coordinates is given as below:

$$ y = \begin{bmatrix} \xi_1 \\ \xi_2 \\ \xi_3 \end{bmatrix} = \begin{bmatrix} L_y h_1 \\ L_y h_2 \\ L_y^2 h_3 \end{bmatrix} \begin{bmatrix} 0 \\ 1 \\ L_y^2 h_3 \end{bmatrix} \begin{bmatrix} u_{ds} \\ u_{qs} \end{bmatrix} $$

Where

$$ h_1(x) = T_c, h_2(x) = \psi_r^2 \text{ and } h_3(x) = \frac{L_y}{L_y^2} $$

Also $L_y h(x)$ is the Lie derivative of a function $h(x)$ along a vector field $f(x) = [f_1(x), f_2(x), \ldots, f_n(x)]$.

By using FLC method to decouple the control inputs, the resulting system is:

$$ y = \begin{bmatrix} \dot{\xi}_1 \\ \dot{\xi}_2 \\ \dot{\xi}_3 \end{bmatrix} = \begin{bmatrix} L_y h_1 \\ L_y h_2 \\ L_y^2 h_3 \end{bmatrix} \begin{bmatrix} 0 \\ 1 \\ L_y^2 h_3 \end{bmatrix} \begin{bmatrix} \xi_{ds} \\ \xi_{qs} \end{bmatrix} $$

And the linear feedback is defined as:

$$ \begin{bmatrix} \xi_{ds} \\ \xi_{qs} \end{bmatrix} = \begin{bmatrix} L_y^2 h_3 \end{bmatrix} \begin{bmatrix} \xi_{ds} \\ \xi_{qs} \end{bmatrix} + \begin{bmatrix} u_{ds} \\ u_{qs} \end{bmatrix} $$

As it is clear, controller generates control signals $\hat{u}_{ds}$ and $\hat{u}_{qs}$ and by applying Eq. (11) main control signals $u_{ds}$ and $u_{qs}$ are produced.

To perform good Tracking dynamic, the model is defined as:

$$ \begin{bmatrix} \xi_{ref}^1 \\ \xi_{ref}^2 \end{bmatrix} = \begin{bmatrix} -a_{ns} & 0 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} h_{ns} \\ h_{ns} \end{bmatrix} + \begin{bmatrix} 0 \\ 0 \end{bmatrix} T_{ref} $$

Where $a_{ns}$, $a_{m2}$ and $a_{m3}$ are positive constants. Also tracking errors are:

$$ e_1 = h_2 - h_{ns} \quad e_2 = h_3 - h_{ns} \quad e_3 = h_3 - h_{ns} $$

3.2 PI fuzzy controller

In this section main part of this paper is presented. At first relationship between $\tilde{u}_{ds}$, $\tilde{u}_{qs}$ control signals and $\hat{u}_{ds}$, $\hat{u}_{qs}$ which are produced by PI controller system, due to Eq.(10) are:

$$ \tilde{u}_{ds} = -l h_1 + \hat{h}_1 e_1 - \hat{u}_{ds} $$

$$ \tilde{u}_{qs} = -l h_1 + \hat{h}_1 e_1 - \hat{u}_{qs} $$

Then the dynamics of the error system with presence of inaccuracies in system modeling or measurements noise or disturbance in load which is presented by $\hat{\的竞争} = \hat{\的竞争}^2 = 0$

$$ \hat{\竞争} + k_1 e_1 + \hat{\竞争} + d_1 = 0 $$

$$ \hat{\竞争} + k_2 e_2 + \hat{\竞争} + d_2 = 0 $$

So:

$$ e_1(t) = \left( \hat{\竞争} + \hat{\竞争}^2 \right) \exp(-k_1 t) $$

$$ e_2(t) = \left( \hat{\竞争} + \hat{\竞争}^2 \right) \exp(-k_2 t) $$

Which its coefficients are:

$$ \alpha_1, \alpha_2 = -k_1 \pm \sqrt{k_2 - 4k_1} $$

According to Eq. 18 and 19, insurance of stability is achieved by choosing $k_1$ $0$ and also $k_2, k_3$ are selected so $\alpha_1, \alpha_2$ have negative signs.

Fuzzy system generates coefficients of PI controller ($k_1, k_2, k_3$).

$$ \tilde{u}_{ds} = k_1^\prime e_1 + k_1^\prime e_1 dt $$

$$ \tilde{u}_{ds} = k_2^\prime e_2 + k_2^\prime e_2 dt $$

For appropriate tracking, fuzzy system input signals are defined as sliding surfaces:

$s_i = k_i e_i$, $s_j = k_p e_j + k_i e_j$  \hspace{1cm} (23)

Presence of inaccuracies ($\hat{d}_1$, $\hat{d}_2$), yields to increase in defined errors and sliding surfaces which are inputs of fuzzy system. So fuzzy system senses inaccuracies and consequently regulates its outputs $\hat{u}_d$, $\hat{u}_s$ to canceling effect of inaccuracies which this regulation is based on experimental knowledge that is presented in tables I and II.

$\hat{u}_d + \hat{d}_1 \to 0$, $\hat{u}_s + \hat{d}_2 \to 0$ \hspace{1cm} (24)

And consequently it causes:

$e_i \to 0$, $e_j \to 0$ \hspace{1cm} (25)

Membership functions are presented in Fig. 2 and Fig. 3. PI controller coefficients adapts due to defined errors by fuzzy system.

4. Simulation

In this part, proposed controller is implemented on induction motor model by simulation. Fig. 4 and 5 represents torque and flux which are controlled by proposed controller in presence of measured noise and disturbance in output torque and flux at 25th second. As it is seen proposed approach controller has a good action in noise effect reduction and disturbance effect cancellation. In order to better evaluation
the performance of proposed method, it is compared to the sliding mode controller (SLMC) and it is implemented to control torque and flux. By using sliding method the control signals due to Eq. 10 are:

\[ \hat{u}_w = -I_h l_f h_{11} + k_e e_1 - k_s \text{sat}(s_1) \]  

\[ \hat{u}_d = -I^2 l_f h_{12} + k_e \hat{e}_2 - k_s \text{sat}(s_2) \] 

Simulated results are shown in Fig. 9. By comparing the proposed controller results to sliding method it is clear that proposed controller acts very better in presence of noise and disturbance.

5. Conclusions

In this paper an adaptive fuzzy PI controller with feedback linearizing method is implemented to controlling flux and torque separately in induction motor. First decoupling of torque and flux which are outputs to be controlled, is achieved by using feedback linearization methodology. Then for reducing the effect of noise and rejection of disturbance or inaccuracy in modeling, main part of controller which is adaptive PI fuzzy controller, is designed. Coefficients of PI controller are determined by defined fuzzy rules due to error dynamic. The main contribution of this paper is effect reduction of noise and disturbance on torque and flux which is based on fuzzy logic and nonlinear control.
